An Algorithm

A finite sequence of rigorous instructions, typically used to solve a class of specific problems or to perform a computation

Algorithm 1 Check Even or Odd

```
1: procedure CHECKEVENORODD( $n$ )  $\triangleright$  Input: Integer  
    $n$   
2:   if  $n$  is divisible by 2 then  
3:     Output: "Even"  
4:   else  
5:     Output: "Odd"  
6:   end if  
7: end procedure
```

DATA

Facts and statistics collected together for reference or analysis.

Data set

A data set (or dataset) is a collection of data.

Entity

An entity is something that exists and can be distinctly identified. For example, in a database of employees, each employee is an entity.

Attributes

An attribute is a characteristic of an entity. For instance, in the context of an employee entity, attributes might include name, employee ID, age, and salary

ABSTRACT. We have developed several algorithms for classifying objects in astronomical images. These algorithms have been used to label stars, galaxies, cosmic rays, plate defects, and other types of objects in sky surveys and other image databases. Our primary goal has been to develop techniques that classify with high accuracy, in order to ensure that celestial objects are not stored in the wrong catalogs. In addition, classification time must be fast due to the large number of classifications and to future needs for on-line classification systems. This paper reports on our results from using decision-tree classifiers to identify cosmic-ray hits in *Hubble Space Telescope* images. This method produces classifiers with over 95% accuracy using data from a single, unpaired image. Our experiments indicate that this accuracy will get even higher if methods for eliminating background noise improve.

k-Nearest Neighbors for automated classification of celestial objects

LI LiLi^{1,2,3†}, ZHANG YanXia¹ & ZHAO YongHeng¹

¹ National Astronomical Observatories, Chinese Academy of Sciences, Beijing 100012, China;

² Department of Physics, Hebei Normal University, Shijiazhuang 050016, China;

³ Weishanlu Middle School, Tianjin 300222, China

The nearest neighbors (NNs) classifiers, especially the *k*-Nearest Neighbors (*k*NNs) algorithm, are among the simplest and yet most efficient classification rules and widely used in practice. It is a nonparametric method of pattern recognition. In this paper, *k*-Nearest Neighbors, one of the most commonly used machine learning methods, work in automatic classification of multi-wavelength astronomical objects. Through the experiment, we conclude that the running speed of the *k*NN classifier is rather fast and the classification accuracy is up to 97.73%. As a result, it is efficient and applicable to discriminate active objects from stars and normal galaxies with this method. The classifiers trained by the *k*NN method can be used to solve the automated classification problem faced by astronomy and the virtual observatory (VO).
